## International Nomenclature in Clinical Chemistry 1972

Modern prevention, diagnosis, and treatment of disease require numerous and sophisticated clinical chemical results.

In order to produce the necessary data, the laboratories employ qualified personnel of different education as well as specialized chemical and physical technology.

In order to evaluate the results clinicians must have some knowledge of chemistry and biochemistry.

Thus, clinicians and clinical chemists alike have to communicate with the basic sciences — albeit to a different degree and with different emphasis.

To facilitate intra- and interdisciplinary communication the International Organization for Standardization (ISO), the International Union of Pure and Applied Physics (IUPAP), the International Union of Pure and Applied Chemistry (IUPAC), and the International Union of Biochemistry (IUB), during the last years, have agreed on a common nomenclature, based on the International System of Units (SI). Already, technology and governments have started to approve and implement the recommendations.

Medicine, including clinical chemistry, cannot afford to remain outside this community of science by maintaining a separate out-dated language. This is the reason why the International Federation of Clinical Chemistry (IFCC) and the Section on Clinical Chemistry of IUPAC have issued recommendations in consonance with those of the abovementioned international bodies (1, 2, 3).

Recently, most of the rules have been restated in an important *Recommendation for Use of SI in Clinical Laboratory Measurements 1972* of the International Committee for Standardization in Hematology, International Federation of Clinical Chemistry, and World Association of (Anatomic and Clinical) Pathology Societies (4). This Recommendation is published on page 93 of the present issue. It will also appear in a number of other clinical chemical, haematological, and clinical pathology journals.

### Main principles

For details of nomenclature the original clinical chemical recommendations should be consulted. However, the outlines are as follows.

1. The *units of measurement* are those given by the International System of Units (5) — SI units. The *base units*, one for each basic kind of quantity, are listed in Table 1.

Tab. 1  
Basic kinds of quantities and base units

Basic kind of quantity English name	SI Base unit	
	English name	Symbol
length	metre	m
mass	kilogram	kg
time	second	s
electric current	ampere	A
thermodynamic temperature	kelvin	K
luminous intensity	candela	cd
amount of substance	mole	mol

*Derived units* are created by multiplication and division of base units, e. g. the coherent derived unit of pressure is kg/(s<sup>2</sup>m), also called pascal (Pa). As regards *units in enzymology* the IUB/IUPAC Recommendations (6) apply.

2. The *preferred unit of volume* is 'litre', symbolized 'l', in accordance with chemical usage. The coherent SI unit is 'cubic metre', symbolized 'm<sup>3</sup>', but litre is more convenient and permitted.

3. The use of *decimal multiples and sub-multiples of SI units* is facilitated by the series of *SI prefixes*; those having exponents of 3 *n*, where *n* is a whole negative or positive number, are preferred (Tab. 2).

Tab. 2  
Decimal multiples and sub-multiples; SI prefixes

Factor	SI prefix		Factor	SI prefix	
	Name	Symbol		Name	Symbol
10 <sup>12</sup>	tera	T	10 <sup>-3</sup>	milli	m
10 <sup>9</sup>	giga	G	10 <sup>-6</sup>	micro	μ
10 <sup>6</sup>	mega	M	10 <sup>-9</sup>	nano	n
10 <sup>3</sup>	kilo	k	10 <sup>-12</sup>	pico	p
			10 <sup>-15</sup>	femto	f
			10 <sup>-18</sup>	atto	a

4. In a given base or derived unit *only one prefix* should be used. If the unit is a fraction the prefix, preferably, is put *in the numerator*; an exception is the base unit kilogram. Thus, mμm → nm, μmol/ml → mmol/l, and μg/g → mg/kg. Note that the volume base of concentration units should be the litre.

5. For quantities comprising components with sufficiently well known chemical structure it is recommended to employ those with *kinds of quantities of a 'molecular nature'*, i. e. based on 'amount of substance' with the unit 'mole'. There is more biochemical and, thus, pathobiological information in stating, e. g., the substance concentration of albumin in serum than in giving its mass concentration: The substance concentration in serum of bilirubins directly shows a useful relationship to that of albumin.

6. The name of a type of quantity should always contain information on 1) *system*, 2) *component*, and 3) *kind of quantity*; the result is a product of 4) *numerical value*, and 5) *unit*. The actual form of the statement may be a sentence like 'the substance concentration of sodium ion in serum was 142 millimoles per litre' or a set of conventions may lead to, e. g., 'S—Sodium ion, substc. = 142 mmol/l'.

7. The complete answer should contain or refer to sufficient information on method in its widest sense (including state of patient), error, reference values ('normal values'), and comments — as well as administrative data.

### Conclusion

The implementation of some of the above recommendations will result in some initial inconveniences. Practical experience from 'converted' countries like the Netherlands, Finland, and Denmark has shown that the problems are surmountable if the change is preceded and followed by education of all types of involved personnel — and occurs with mutual co-operation.

The advantages of the new system are the easier access to other branches of pure and applied science, more useful information, and the eventual substitution of current diversity in expression with a single form for presentation of clinical chemical data.
