Abstract

This paper addresses a general class of two-stage stochastic programs with integer recourse and discrete distributions. We exploit the structure of the value function of the second stage integer problem to develop a novel global optimization algorithm. The proposed scheme departs from those in the current literature in that it avoids explicit enumeration of the search space while guaranteeing finite termination. Our computational results indicate superior performance of the proposed algorithm in comparison to the existing literature.

Keywords: stochastic integer programming, branch and bound, finite algorithms.

1 Introduction

Under the two-stage stochastic programming paradigm, the decision variables of an optimization problem under uncertainty are partitioned into two sets. The first stage variables are those that have to be decided before the actual realization of the uncertain parameters. Subsequently, once the random events have presented themselves, further design or operational policy improvements can be made by selecting, at a certain cost, the values of the second stage or *recourse* variables. The goal is to determine first stage decisions such that the sum of first stage cost and the expected recourse cost is minimized. A standard formulation of the two stage stochastic program is as follows [4, 28]:

$$(2SSP) : \quad z = \min \quad c^T x + E_{\omega \in \Omega}[Q(x, \omega)] \quad (1)$$

$$\text{s.t.} \quad x \in X,$$

with

$$Q(x, \omega) = \min \quad f(\omega)^T y \quad (2)$$

$$\text{s.t.} \quad D(\omega)y \geq h(\omega) + T(\omega)x$$

$$y \in Y,$$

where $X \subseteq \mathbb{R}^{n_1}$, $c \in \mathbb{R}^{n_1}$, and $Y \subseteq \mathbb{R}^{n_2}$. Here, ω is a random variable from a probability space $(\Omega, \mathcal{F}, \mathcal{P})$ with $\Omega \subseteq \mathbb{R}^k$, $f : \Omega \rightarrow \mathbb{R}^{n_2}$, $h : \Omega \rightarrow \mathbb{R}^{m_2}$, $D : \Omega \rightarrow \mathbb{R}^{m_2 \times n_2}$, $T : \Omega \rightarrow \mathbb{R}^{m_2 \times n_1}$. Problem (1) with variables x constitute the first stage which needs to be decided prior to the realization of the uncertain parameters ω ; and (2) with variables y constitute the second stage.

In the presence of linear constraints and variables only, problem (2SSP) is referred to as a two stage stochastic *linear* program. For a given value of the first stage variables x , the second stage problem decomposes into independent subproblems, one for each realization of the uncertain parameters. This decomposability property, along with the convexity of the second stage value function $Q(\cdot, \omega)$ [55, 56], has been exploited to develop a number of decomposition-based algorithms [5, 20, 26, 41, 54] as well as gradient-based algorithms [17, 46]. For an extensive discussion of stochastic programming, the reader is referred to standard text books [4, 25, 28, 37].

In contrast to stochastic linear programming, the study of stochastic *integer* programs, those that have integrality requirements in the second stage, is very much in its infancy. These problems arise when the second stage involves, for example, scheduling decisions [14], routing decisions [47], resource acquisition decisions [3], fixed-charge costs [6], and change-over costs [10]. In addition, binary variables in the second stage can also arise in the modeling of risk objectives in stochastic linear programming [29]. The main difficulty in solving stochastic integer programs is that the value function $Q(\cdot, \omega)$ is not necessarily convex but only lower semicontinuous (l.s.c.) [7, 49, 43]. Thus, the standard decomposition approaches that work nicely for stochastic linear programs, break down when second stage integer variables are present. As an illustration of the non-convex nature of stochastic integer programs, consider the following example from [45]:

$$(EX) : \quad \min \quad -1.5x_1 - 4x_2 + E[Q(x_1, x_2, \omega_1, \omega_2)]$$

$$\text{s.t.} \quad 0 \leq x_1, x_2 \leq 5,$$

where

$$Q(x_1, x_2, \omega_1, \omega_2) = \min \quad -16y_1 - 19y_2 - 23y_3 - 28y_4$$

$$\text{s.t.} \quad 2y_1 + 3y_2 + 4y_3 + 5y_4 \leq \omega_1 - \frac{1}{3}x_1 - \frac{2}{3}x_2$$

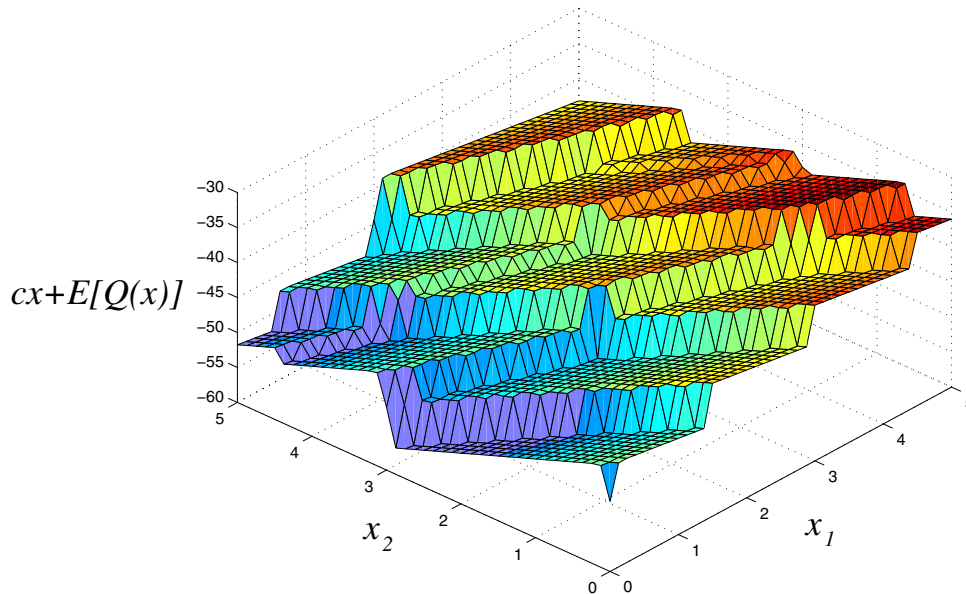

Figure 1: Objective function of (EX)

$$6y_1 + y_2 + 3y_3 + 2y_4 \leq \omega_2 - \frac{2}{3}x_1 - \frac{1}{3}x_2$$

$$y_1, y_2, y_3, y_4 \in \{0, 1\},$$

and $(\omega_1, \omega_2) \in \{5, 15\} \times \{5, 15\}$ with a uniform probability distribution. Figure 1 shows the objective function of (EX) in the space of the first stage variables. The highly discontinuous (lower semicontinuous) and multi-extremal nature of the function is clearly observed. Thus, in general, stochastic integer programming constitutes globally minimizing a highly non-convex function.

For problems where the second stage recourse matrix D possesses a special structure known as *simple recourse*, Haneveld *et al.* [18, 19] proposed solution schemes based upon the construction of the convex hull of the second stage value function. For more general recourse structure, Laporte and Louveaux [30] proposed a decomposition-based approach for stochastic integer programs when the first stage variables are pure binary. This restriction allows for the construction of optimality cuts that approximate the non-convex second stage value function at only the binary first stage solutions (but not necessarily at other points). The authors proposed a branch and bound algorithm approach to search the space of the first stage variables for the global optimal solution, while using the optimality cuts to approximate the second stage value function. Finite termination of the algorithm is obvious since the number of first stage solutions is finite. The method has been successfully used in solving two-stage stochastic

location-routing problems [31, 32, 33, 34]. Unfortunately, the algorithm is not applicable if any of the first stage variables are continuous. Caroe and Tind [12] generalized this algorithm to handle cases with mixed-integer first and second stage variables. The method required the use of non-linear integer programming dual functions to approximate the second stage value function in the space of the first stage variables. The resulting master problem then consists of non-linear (possibly discontinuous) cuts, and the authors admit that no practicable method for its solution is known [45].

Caroe [9, 11] used the scenario decomposition approach of Rockafellar and Wets [39] to develop a branch and bound algorithm for stochastic integer programs. This method solves the Lagrangian dual, obtained by dualizing the non-anticipativity constraints, as the lower bounding problem within a standard branch and bound framework. The subproblems of the Lagrangian dual correspond to the scenarios and include variables and constraints from both first stage and second stage. Consequently, these subproblems are more difficult to solve than in Benders-based methods, where a subproblem corresponds to only the second stage problem for a particular scenario. Furthermore, although the Lagrangian dual provides very tight bounds, its solution requires the use of subgradient methods and is computationally expensive. A major limitation of this approach is that finite termination is guaranteed only if the first stage variables are purely discrete, or if an ϵ -optimal termination criterion with $\epsilon > 0$ is used [9, 11].

More recently, Schultz *et al.* [45] proposed a finite scheme for two-stage stochastic programs with discrete distributions and pure integer second stage variables. For this problem, the authors of [45] observe that only integer values of the right hand side parameters of the second stage problem are relevant. This fact is used to identify a countable set in the space of the first stage variables containing the optimal solution. In [45], the authors propose complete enumeration of this set to search for the optimal solution. Evaluation of an element of the set requires the solution of second stage integer subproblems corresponding to all possible realizations of the uncertain parameters. Thus, explicit enumeration of all elements is, in general, computationally prohibitive.

For a more detailed discussion on various algorithms for stochastic integer programming, the reader is referred to the recent surveys of van der Vlerk and co-workers [53, 44, 50].

In this paper, we develop a branch and bound algorithm for the global optimization of two-stage stochastic integer programs with discrete distributions, mixed-integer first stage variables, and pure integer second stage variables. The main difficulty with applying branch and bound to a (semi-)continuous domain is that the resulting approach may not be finite, *i.e.*, infinitely many subdivisions may be required for the lower and upper bounds to become exactly equal. With the exception of one [45], all existing practical algorithms for general stochastic integer programming also rely on applying branch and bound to the first stage variables to deal with the non-convexities of the value function. Consequently, finite termination of these algorithms is not guaranteed unless the first stage variables, *i.e.*, the search space, is purely discrete. For the algorithm proposed

in this paper, we prove finite termination. The method differs from the finite algorithm of [45], in that it avoids explicit enumeration of all discontinuous pieces of the value function. Furthermore, the proposed method allows for uncertainties in the cost parameters and the constraint matrix in addition to the right hand sides of the recourse problem.

The key concept behind our development is to reformulate the problem via a variable transformation that induces special structure to the discontinuities of the value function. This structure is exploited through: (a) a branching strategy that isolates the discontinuous pieces and eliminates discontinuities, and (b) a bounding strategy that provides an exact representation of the value function of the second stage integer program in the absence of discontinuities. Finiteness of the method is a consequence of the fact that, within a bounded domain, there is only a finite number of such discontinuous pieces of the value function. The issue of finiteness is not only of theoretical significance – our computational results indicate that the proposed algorithm performs vastly superior to existing strategies in the literature.

The remainder of the paper is organized as follows. Section 2 specifies the assumptions required for the proposed algorithm. In Section 3, we present the transformed problem and discuss its relation to the original problem. Some structural results on the transformed problem are presented in Section 4. These results are used to develop a branch and bound algorithm in Section 5. Section 6 provides the proof of finiteness of the proposed algorithm. Some enhancements and extensions of the algorithm are suggested in Section 7. Finally, computational results are presented in Section 8.

2 Assumptions

In this paper, we address instances of (2SSP) under the following assumptions:

- (A1) The uncertain parameter ω follows a discrete distribution with finite support $\Omega = \{\omega^1, \dots, \omega^S\}$ with $\Pr(\omega = \omega^s) = p^s$.
- (A2) The second stage variables y are purely integer, *i.e.*, $y \in \mathbb{Z}^{n_2}$.
- (A3) The technology matrix T linking the first and second stage problems is deterministic, *i.e.*, $T(\omega) = T$.

Assumption (A1) is justified by the results of Schultz [43] who showed that, if ω has a continuous distribution, the optimal solution to the problem can be approximated within any given accuracy by the use of discrete distributions. Extensions of the proposed algorithm when assumptions (A2) and (A3) are not satisfied are briefly discussed in Section 7.

The uncertain problem parameters $(f(\omega), D(\omega), h(\omega))$ associated with a particular realization ω^s (a scenario), will be succinctly denoted by (f^s, D^s, h^s) with associated probability p^s . Without any loss of generality, we assume the first stage variables to be purely continuous. Mixed-integer first stage variables can

be handled in the framework to follow without any added conceptual difficulty. We can then state the problem as follows:

$$(2SSIP) : \quad z = \min \quad cx + \sum_{s=1}^S p^s Q^s(x) \\ \text{s.t.} \quad x \in X,$$

with

$$Q^s(x) = \min \quad f^s y \\ \text{s.t.} \quad D^s y \geq h^s + Tx \\ y \in Y \cap \mathbb{Z}^{n_2},$$

where $X \subseteq \mathbb{R}^{n_1}$, $c \in \mathbb{R}^{n_1}$, $T \in \mathbb{R}^{m_2 \times n_1}$, and $Y \subseteq \mathbb{R}^{n_2}$. For each $s = 1, \dots, S$, $f^s \in \mathbb{R}^{m_2}$, $h^s \in \mathbb{R}^{m_2}$, and $D^s \in \mathbb{R}^{m_2 \times n_2}$. Note that the expectation operator has been replaced by a probability weighted finite sum, and the transposes have been eliminated for simplicity.

We make the following additional assumptions for (2SSIP):

- (A4) The first stage constraint set X is non-empty and compact.
- (A5) $Q^s(x) < \infty$ for all $x \in \mathbb{R}^{n_1}$ and all s .
- (A6) For each s , there exists $u^s \in \mathbb{R}_+^{m_2}$ such that $u^s D^s \leq f^s$.
- (A7) For each s , the second stage constraint matrix is integral, *i.e.*, $D^s \in \mathbb{Z}^{m_2 \times n_2}$.

Assumption (A5) is known as the *complete recourse* property [55]. In fact, we only need relatively complete recourse, *i.e.*, $Q^s(x) < \infty$ for all $x \in X$ and all s . Since X is compact, relatively complete recourse can always be accomplished by adding penalty inducing artificial variables to the second stage problem. However, we shall assume complete recourse for simplicity of exposition. Assumption (A6) guarantees $Q^s(x) > -\infty$ [43]. Thus, $Q^s(x)$ is finite valued and (2SSIP) is well-defined. Assumption (A7) can be satisfied by appropriate scaling whenever the matrix elements are rational.

For a given value of the first stage variables x , the problem decomposes into S integer programs $Q^s(x)$. It is implicitly assumed that these “small” integer subproblems are easier to solve than the deterministic equivalent. The proposed methodology is independent of the oracle required to solve the integer subproblems. For example, the Gröbner basis framework described in [45] to solve many similar integer programs, can be used in this context.

Note that, for each s , $Q^s(x)$ is the value function of an integer program, and is well known to be lower semicontinuous (l.s.c) with respect to x . Blair and Jeroslow [7, 8] showed that such value functions are, in general, continuous only over certain cones in the space of x and the discontinuities lie along the

boundaries of these cones. Existing branch and bound methods [30, 9, 11] for stochastic integer programs attempt to partition the space of first stage variables by branching on one variable at a time. In this way, the first stage variable space is partitioned into (hyper)rectangular cells. Since the discontinuities are, in general, not orthogonal to the variable axes, there would always be some rectangular partition that contains a discontinuity in the interior. Thus, in the case of continuous first stage variables, it might not be possible for the lower and upper bounds to converge for such a partition, unless the partition is arbitrarily small. This would require infinite partitioning of the first stage variables and only a convergent (*i.e.*, possibly infinite) scheme. In general, it is not obvious how one can partition the search space by subdividing *along* the discontinuities within a branch and bound framework.

Next, we propose a transformation of the problem that causes the discontinuities to be orthogonal to the variable axes. Thus, a rectangular partitioning strategy can potentially isolate the discontinuous pieces of the value function, thereby allowing upper and lower bounds to collapse finitely. This is the key to the subsequent development of a finite branch and bound algorithm.

3 Problem Transformation

Instead of (2SSIP), we propose to solve the following problem:

$$\begin{aligned} \text{(TP)} : \quad & \min f(\chi) \\ & \text{s.t. } \chi \in \mathcal{X} \end{aligned}$$

where

$$\begin{aligned} f(\chi) &= \Phi(\chi) + \bar{\Psi}(\chi), \\ \bar{\Psi}(\chi) &= \sum_{s=1}^S p^s \Psi^s(\chi), \\ \Phi(\chi) &= \min\{cx \mid Tx = \chi, x \in X\}, \\ \Psi^s(\chi) &= \min\{f^s y \mid D^s y \geq h^s + \chi, y \in Y \cap \mathbb{Z}^{n_2}\}, \text{ and} \\ \mathcal{X} &= \{\chi \in \mathbb{R}^{m_2} \mid \chi = Tx, x \in X\}. \end{aligned}$$

The variables χ are known as the “tender variables” in the stochastic programming literature. These are the variables that link the first and second stage problems together. Instead of the first stage variables, we propose to search the space of the tender variable for global optima. The following results establish the existence of a solution of problem (TP), and its relation to the original problem (2SSIP).

Theorem 3.1. *There exists an optimal solution to problem (TP).*

Proof: It follows from Assumption (A5), and the results in [7, 8, 43] that $\Psi^s(\cdot)$ is finite valued and l.s.c. $\Phi(\cdot)$ is the value function of a linear program, and

is therefore piece-wise linear and convex (cf. [1]). Thus, $f(\cdot)$ is a positive linear combination of real valued l.s.c functions, and is therefore l.s.c (by Fatou's Lemma cf. [40]). Since X is non-empty compact (A4), and T is a linear transformation, we have \mathcal{X} is nonempty and compact. The claim then follows from Weierstrass theorem (cf. [21]). \square

Theorem 3.2. *Let χ^* be an optimal solution of (TP). Then $x^* \in \operatorname{argmin}\{cx \mid x \in X, Tx = \chi^*\}$ is an optimal solution of (2SSIP). Furthermore, the optimal objective values of the two problems are equal.*

Proof: First, note that, for any χ and x such that $Tx = \chi$, we have $\Psi^s(\chi) = Q^s(x)$ for all s . Then, from the definition of x^* and $\overline{\Psi}(\cdot)$, we have

$$\Phi(\chi^*) + \overline{\Psi}(\chi^*) = cx^* + \sum_{s=1}^S p^s Q^s(x^*). \quad (3)$$

We shall now prove the claim by contradiction. Suppose that x^* is not an optimal solution to (2SSIP). Then, there exists $x' \in X$ such that

$$cx' + \sum_{s=1}^S p^s Q^s(x') < cx^* + \sum_{s=1}^S p^s Q^s(x^*). \quad (4)$$

Now, construct $\chi' = Tx'$ and note that $\chi' \in \mathcal{X}$. Since $x' \in \{x \mid x \in X, Tx = \chi'\}$, we have $f(\chi') \leq cx'$. Also, $\Psi^s(\chi') = Q^s(x')$ for all s . Equations (3) and (4), then, imply that

$$\Phi(\chi') + \overline{\Psi}(\chi') < \Phi(\chi^*) + \overline{\Psi}(\chi^*).$$

Thus, we have a contradiction. Equation (3) also establishes that the objective values of the two problems are equal. \square

Theorem 3.2 implies that we can solve (2SSIP) by solving (TP) with respect to the tender variables $\chi \in \mathcal{X}$. Typically, \mathcal{X} has smaller dimension than X . More importantly, this transformation induces a special structure to the discontinuities in the problem. These structural results are discussed next.

4 Structural Properties

Let $\Psi^s(\chi_j)$ denote $\Psi^s(\chi)$ as a function of the j th component ($j = 1, \dots, m_2$) of χ . Further, we use $\operatorname{cl}(X)$, $\partial(X)$, and $\dim(X)$ to denote the closure, the relative boundary, and the dimension of a set X , respectively. The following result is well known (cf. [36]).

Lemma 4.1. *For any $s = 1, \dots, S$, and $j = 1, \dots, m_2$, $\Psi^s(\chi_j)$ is l.s.c and non-decreasing in χ_j .*

Schultz *et al.* [45] proved that the second stage value function is constant over certain subsets of the x -space. Next, we prove a similar result in the space of the tender variables.

Lemma 4.2. *For any $k_j^s \in \mathbb{Z}$, $\Psi^s(\chi_j)$ is constant over the interval $\chi_j \in (k_j^s - h_j^s - 1, k_j^s - h_j^s]$ for all $s = 1, \dots, S$ and $j = 1, \dots, m_2$.*

Proof: Since by assumption (A7), D^s is integral, the j th constraint $(D^s y)_j \geq h_j^s + \chi_j$ implies $(D^s y)_j \geq \lceil h_j^s + \chi_j \rceil$. Thus, for any $k_j^s \in \mathbb{Z}$, $\Psi^s(\chi_j)$ is constant over regions $\{(h_j^s + \chi_j) | \lceil h_j^s + \chi_j \rceil = k_j^s\} = \{(h_j^s + \chi_j) | k_j^s - 1 < h_j^s + \chi_j \leq k_j^s\}$. Equivalently, $\Psi^s(k_j^s)$ is constant over intervals $\chi_j \in (k_j^s - h_j^s - 1, k_j^s - h_j^s]$ with $k_j^s \in \mathbb{Z}$. \square

Definition 4.3. *Let B be a subset of \mathbb{R}^n and I be a set of indices. The collection of sets $\mathcal{M} := \{M_i | i \in I\}$, where $M_i \subseteq B$, is called a partitioning of B if $B = \cup_{i \in I} M_i$ and $M_i \cap M_j = \partial(M_i) \cap \partial(M_j)$ for all $i, j \in I, i \neq j$.*

Theorem 4.4. *Let $\mathbf{k} = (k_1^1, \dots, k_j^s, \dots, k_{m_2}^S)^T \in \mathbb{Z}^{Sm_2}$ be a vector of integers. For a given \mathbf{k} , let*

$$\mathcal{C}(\mathbf{k}) := \{\chi \in \mathbb{R}^{m_2} | \chi \in \cap_{s=1}^S \prod_{j=1}^{m_2} (k_j^s - h_j^s - 1, k_j^s - h_j^s]\}.$$

The following assertions hold:

- (i) *if $\mathcal{C}(\mathbf{k}) \neq \emptyset$, then $\text{cl}(\mathcal{C}(\mathbf{k}))$ is a full dimensional hyper-rectangle, i.e., $\dim(\mathcal{C}(\mathbf{k})) = m_2$,*
- (ii) *the collection $\{\mathcal{C}(\mathbf{k}) | \mathbf{k} \in \mathbb{Z}^{Sm_2}\}$ forms a partitioning of \mathbb{R}^{m_2} ,*
- (iii) *if $\mathcal{C}(\mathbf{k}) \neq \emptyset$, then $\overline{\Psi}(\chi)$ is constant over $\mathcal{C}(\mathbf{k})$.*

Proof: Part (i): Note that $\prod_{j=1}^{m_2} [k_j^s - h_j^s - 1, k_j^s - h_j^s]$ is the Cartesian product of intervals, and hence is a hyper-rectangle. The orthogonal intersection of all such hyper-rectangles is also a hyper-rectangle. The first part of the claim then follows from the well known facts that for convex sets C_i with $i \in I$, $\text{cl}(\prod_{i \in I} C_i) = \prod_{i \in I} \text{cl}(C_i)$, and $\text{cl}(\cap_{i \in I} C_i) = \cap_{i \in I} \text{cl}(C_i)$ (cf. [38]). To see that such a hyper-rectangle is full-dimensional, the reader can verify that any $\mathcal{C}(\mathbf{k}) \neq \emptyset$ can be written as $\mathcal{C}(\mathbf{k}) = \prod_{j=1}^{m_2} \cap_{s=1}^S (k_j^s - h_j^s - 1, k_j^s - h_j^s]$. For each j , $\cap_{s=1}^S (k_j^s - h_j^s - 1, k_j^s - h_j^s]$ is the finite intersection of unit-length intervals which are left-open and right-closed. Thus, this intersection is itself a positive length interval. $\mathcal{C}(\mathbf{k})$ is then the Cartesian product of such positive length intervals and is hence full-dimensional.

Part (ii): It can be easily verified that for any $\chi \in \mathbb{R}^{m_2}$, there exists $\mathbf{k} \in \mathbb{Z}^{Sm_2}$ such that $\chi \in \mathcal{C}(\mathbf{k})$. Furthermore, for $\mathbf{k} \neq \mathbf{k}'$, $\mathcal{C}(\mathbf{k})$ and $\mathcal{C}(\mathbf{k}')$ are disjoint. Thus, $\{\mathcal{C}(\mathbf{k}) | \mathbf{k} \in \mathbb{Z}^{Sm_2}\}$ forms a partitioning of \mathbb{R}^{m_2} .

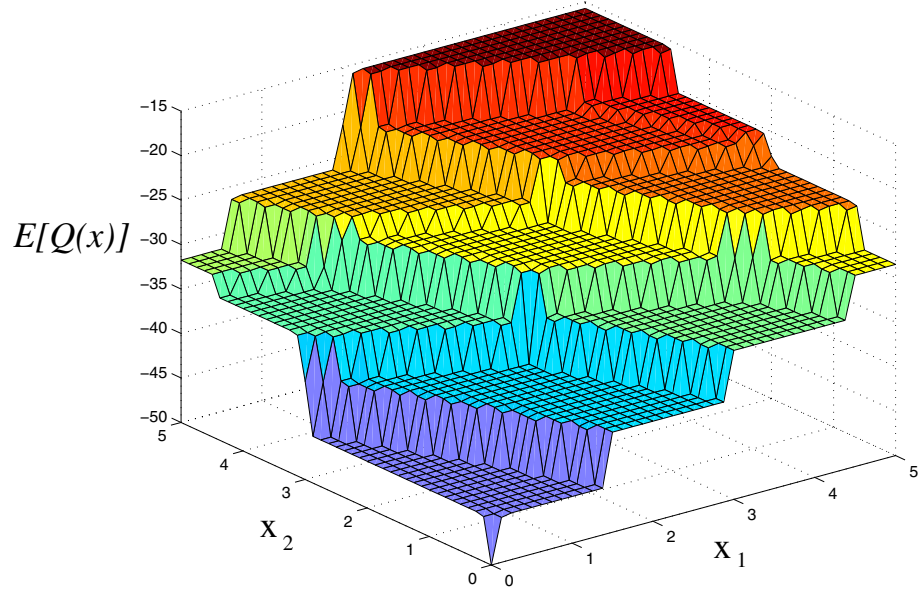

Figure 2: The Second Stage Value Function of (EX) over X

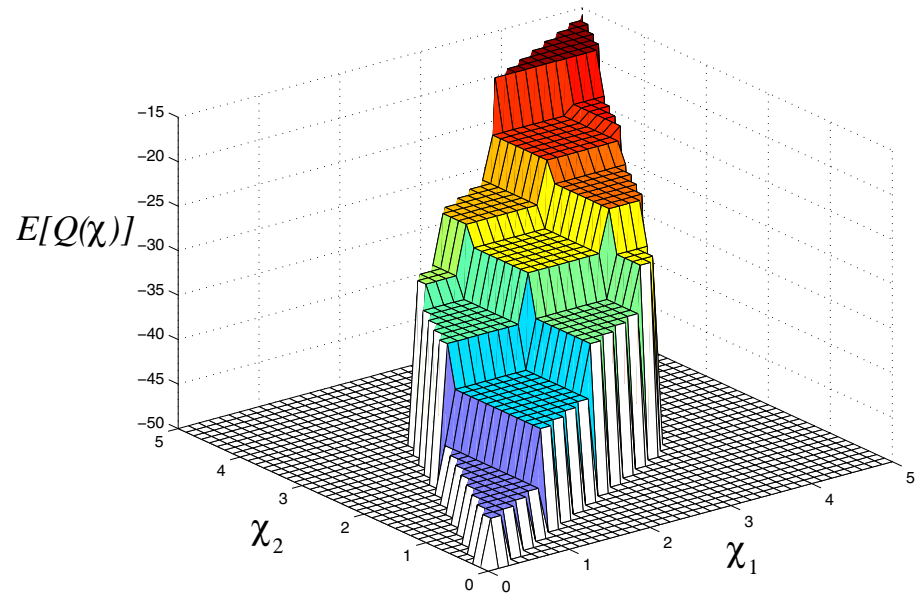

Figure 3: The Second Stage Value Function of (EX) over X'

Part (iii): For a given \mathbf{k} , it follows from Lemma 4.2, that for any s , $\Psi^s(\chi)$ is constant over the hyper-rectangle $\Pi_{j=1}^{m_2} (k_j^s - h_j^s - 1, k_j^s - h_j^s]$. Since $\mathcal{C}(\mathbf{k})$ is a non-empty subset of all such hyper-rectangles (for all s), each $\Psi^s(\chi)$ is constant over $\mathcal{C}(\mathbf{k})$, and so is $\overline{\Psi}(\chi)$. \square

The above result establishes that the second stage expected value function is piece wise constant over (neither open nor closed) rectangular regions in the space of the tender variables χ . Thus, the discontinuities can only lie at the boundaries of these regions and, therefore, are all orthogonal to the variable axes. This is not the case, in general, if we consider the value function in the space of the original first stage variables. To illustrate this, we plot the second stage expected value function for the example problem (EX) considered in Section 1, in the space of the original first stage variables (Figure 2) and in the space of the tender variables (Figure 3). The change in the orientation of the discontinuities is clear. Notice that the feasible region \mathcal{X} is a linear transformation of X .

Next, we establish the finiteness of the partitioning when the underlying set is compact.

Theorem 4.5. *Let $\mathcal{X} \in \mathbb{R}^{m_2}$ and $\mathcal{K} := \{\mathbf{k} \in \mathbb{Z}^{S m_2} | \mathcal{C}(\mathbf{k}) \cap \mathcal{X} \neq \emptyset\}$. Then, if \mathcal{X} is compact, $|\mathcal{K}| < \infty$.*

Proof: Since \mathcal{X} is compact, we can obtain finite bounds l_j and u_j such that $l_j \leq \chi_j \leq u_j$ for all $\chi \in \mathcal{X}$. Now, suppose for some $\mathbf{k} = (k_1^1, \dots, k_j^s, \dots, k_{m_2}^S)^T$, there exists $\bar{\chi} \in \mathcal{C}(\mathbf{k}) \cap \mathcal{X}$. Then, from the definition of $\mathcal{C}(\mathbf{k})$ and the fact that \mathcal{X} is compact, we must have for each j : $l_j \leq k_j^s - h_j^s$ for all s , which implies $k_j^s \geq \lceil l_j + h_j^s \rceil$. Similarly, we also have $k_j^s - h_j^s - 1 \leq u_j$, which then implies $k_j^s \leq \lfloor u_j + h_j^s + 1 \rfloor$. Thus

$$\lceil l_j + h_j^s \rceil \leq k_j^s \leq \lfloor u_j + h_j^s + 1 \rfloor.$$

We have bounded each component of the vector \mathbf{k} for which $\mathcal{C}(\mathbf{k}) \cap \mathcal{X} \neq \emptyset$. Since \mathbf{k} is an integer vector, there can only be a finite number of these that satisfy the above bounds. Thus, the claim follows. \square

The above result along with Theorem 4.4 implies that the compact set \mathcal{X} is completely covered by a finite number of rectangular partitions, over each of which the second stage value function is constant. In Section 5, we exploit this property to develop a finite branch and bound algorithm for (TP).

5 A Branch and Bound Algorithm

A major issue in applying branch and bound over continuous domains is that the resulting approach may not be finite but merely convergent, *i.e.*, infinitely many subdivision may be required to make the lower bound exactly equal to the upper bound. In addition, for our problem (TP), we need to be able to deal with the

discontinuous nature of the objective function. The challenge here is to identify combinations of lower-bounding and branching techniques that can handle the discontinuous objective function and yield a finite algorithm. Towards this end, we exploit the structural results of Section 4 by partitioning the search space into regions of the form $\prod_{j=1}^{m_2} (l_j, u_j]$, where l_j is a point at which the second stage value function $\bar{\Psi}(\chi_j)$ may be discontinuous. Recall, that $\bar{\Psi}(\chi_j)$ can only be discontinuous at points χ_j where $(h_j^s + \chi_j)$ is integral for some s . Thus we partition our search space along such values of χ . Branching in this manner, we can isolate regions over which the second stage value function is constant, and hence solve the problem exactly.

We shall now present a formal statement of a prototype branch and bound algorithm for problem (TP). The words in italic letters constitute the critical operations of the algorithm and will be discussed in subsequent subsections. The following notation is used in the description.

Notation:

\mathcal{L}	List of open subproblems
k	Iteration number; also used to indicate the subproblem selected
\mathcal{P}^k	Partition corresponding to k
α^k	Upper bound obtained at iteration k
β^k	Lower bound on subproblem k
χ^k	A feasible solution to subproblem k
U	Upper bound on the global optimal value
L	Lower bound on the global optimal value
χ^*	Candidate for the global optima

The Algorithm

Initialization:

Preprocess the problem by constructing the hyper-rectangle $\mathcal{P}^0 := \prod_{j=1}^{m_1} (l_j^0, u_j^0] \supseteq \mathcal{X}$. Add the problem $\min\{f(\chi) | \chi \in \mathcal{X} \cap \mathcal{P}^0\}$ to the list \mathcal{L} of open subproblems.

Set $U \leftarrow +\infty$ and $k \leftarrow 0$.

Iteration k :

Step $k.1$: If $\mathcal{L} = \emptyset$, terminate with solution χ^* , otherwise *select* a subproblem k , defined as $\inf\{f(\chi) | \chi \in \mathcal{X} \cap \mathcal{P}^k\}$, from the list \mathcal{L} of currently open subproblems. Set $\mathcal{L} \leftarrow \mathcal{L} \setminus \{k\}$. Note, that the min has been replaced by inf since the feasible region of the problem is not necessarily closed.

Step $k.2$: *Bound* the infimum of subproblem k from below, *i.e.*, find β^k satisfying $\beta^k \leq \inf\{f(\chi) | \chi \in \mathcal{X} \cap \mathcal{P}^k\}$. If $\mathcal{X} \cap \mathcal{P}^k = \emptyset$, $\beta^k = +\infty$ by convention. Determine a feasible solution $\chi^k \in \mathcal{X}$ and compute an upper bound $\alpha^k \geq \min\{f(\chi) | \chi \in \mathcal{X}\}$ by setting $\alpha^k = f(\chi^k)$.

Step k.2.a: Set $L \leftarrow \min_{i \in \mathcal{L} \cup \{k\}} \beta^i$.

Step k.2.b: If $\alpha^k < U$, then $\chi^* \leftarrow \chi^k$ and $U \leftarrow \alpha^k$.

Step k.2.c: Fathom the subproblem list, *i.e.*, $\mathcal{L} \leftarrow \mathcal{L} \setminus \{i \mid \beta^i \geq U\}$. If $\beta^k \geq U$, then goto Step k.1 and select another subproblem.

Step k.3: *Branch*, by partitioning \mathcal{P}^k into \mathcal{P}^{k_1} and \mathcal{P}^{k_2} . Set $\mathcal{L} \leftarrow \mathcal{L} \cup \{k_1, k_2\}$, *i.e.*, append the two subproblems $\inf\{f(\chi) \mid \chi \in \mathcal{X} \cap \mathcal{P}^{k_1}\}$ and $\inf\{f(\chi) \mid \chi \in \mathcal{X} \cap \mathcal{P}^{k_2}\}$ to the list of open subproblems. For selection purposes, set $\beta^{k_1}, \beta^{k_2} \leftarrow \beta^k$. Set $k \leftarrow k + 1$ and goto Step k.1.

5.1 Preprocessing

As mentioned earlier, we shall only consider partitions of the form $\Pi_{j=1}^{m_2}(l_j, u_j]$, where l_j is such that $(h_j^s + l_j)$ is integral for some s . We can then construct a partition $\mathcal{P}^0 := \Pi_{j=1}^{m_1}(l_j^0, u_j^0] \supset \mathcal{X}$ in the following manner:

- Construct a closed partition $\Pi_{j=1}^{m_2}[l_j, u_j] \supseteq \mathcal{X}$ as follows: for each component j of χ , set $l_j = \min\{\chi_j \mid \chi \in \mathcal{X}\}$ and $u_j = \max\{\chi_j \mid \chi \in \mathcal{X}\}$. Typically, \mathcal{X} is polyhedral and so the above problems are linear programs.
- For each s and j , find $k_j^s \in \mathbb{Z}$ such that $k_j^s - h_j^s - 1 < l_j \leq k_j^s - h_j^s$. If $l_j + h_j^s$ is integral, set $k_j^s = l_j + h_j^s$, otherwise set $k_j^s = \lfloor l_j + h_j^s + 1 \rfloor$. Let $l_j^0 = \max_{s=1, \dots, S} \{k_j^s - h_j^s - 1\}$.
- Set $u_j^0 = u_j$.

Above, we have relaxed l_j to l_j^0 such that l_j^0 is the closest point to l_j where $(l_j^0 + h_j^s)$ is integral for some s . From now on, whenever convenient, we shall denote partitions of the form $\Pi_{j=1}^{m_1}(l_j, u_j]$ by $(l, u]$ with $l = (l_1, \dots, l_{m_2})^T$, and $u = (u_1, \dots, u_{m_2})^T$.

5.2 Selection

In Step k.1 of iteration k , we need to select a subproblem, from the list of open subproblems \mathcal{L} , to be considered for bounding and further partitioning. A critical condition for convergence of a branch and bound algorithm is that this selection operation be *bound improving* [22]. This is accomplished by choosing the subproblem that attains the least lower bound, *i.e.*, select $k \in \mathcal{L}$ such that $\beta^k = L$.

5.3 Lower Bounding

For a given partition $\mathcal{P}^k := \Pi_{j=1}^{m_2}(l_j^k, u_j^k]$ where l_j is such that $(h_j^s + l_j)$ is integral for some s , we can obtain a lower bound on the corresponding subproblem by

solving:

$$(LB) : \quad f_L(\mathcal{P}^k) = \min \quad cx + \theta \quad (5)$$

$$\text{s.t.} \quad x \in X, Tx = \chi$$

$$l^k \leq \chi \leq u^k$$

$$\theta \geq \sum_{s=1}^S p^s \Psi^s(l^k + \epsilon), \quad (6)$$

where

$$\Psi^s(\chi) = \min \quad f^s y \quad (7)$$

$$\text{s.t.} \quad D^s y \geq h^s + \chi$$

$$y \in Y \cap \mathbb{Z}^{n_2}.$$

In problem (LB), ϵ is sufficiently small such that $\Psi^s(\cdot)$ is constant over $(l^k, l^k + \epsilon]$ for all s . Since we have exactly characterized the regions over which the $\Psi^s(\cdot)$ is constant, we can calculate this ϵ *a priori*. A procedure for this is outlined next.

Calculation of ϵ :

- Do for $j = 1, \dots, m_2$:
 - Set $s = 1, \Xi = \emptyset$. Choose $k_j^1 \in \mathbb{Z}$.
 - Let $\chi_j^0 = k_j^1 - h_j^1 - 1$ and $\chi_j^1 = \chi_j^0 + 1$.
 - Set $\Xi \leftarrow \Xi \cup \{\chi_j^0, \chi_j^1\}$.
 - Do for $s = 2, \dots, S$:
 - Choose $k_j^s \in \mathbb{Z}$ such that $\chi_j^0 < k_j^s - h_j^s \leq \chi_j^1$, *i.e.*, set $k_j^s = \lfloor \chi_j^1 + h_j^s \rfloor$.
 - Let $\chi_j^s = k_j^s - h_j^s$.
 - If $\Xi \cap \{\chi_j^s\} = \emptyset$, then set $\Xi \leftarrow \Xi \cup \{\chi_j^s\}$.
 - End Do.
 - Order the elements of Ξ such that $\chi_j^0 = \xi_j^0 < \xi_j^1 < \dots < \xi_j^n = \chi_j^1$, with $n \leq S$.
 - Let $\epsilon_j = \min_{i=1, \dots, n} \{\xi_j^i - \xi_j^{i-1}\}$.
- End Do.
- Set $\epsilon = 0.5 \times \min_{j=1, \dots, m_2} \{\epsilon_j\}$.

In the above procedure, we first determine an interval $(\chi_j^0, \chi_j^1]$ such that $\lceil h_j^1 + \chi_j \rceil$, and hence $\Psi^1(\chi_j)$, is constant for all $\chi_j \in (\chi_j^0, \chi_j^1]$. Then, for each $s = 2, \dots, S$, we find χ_j^s such that $\lceil h_j^s + \chi_j \rceil$, and hence $\Psi^s(\chi_j)$, is constant for all $\chi_j \in (\chi_j^0, \chi_j^s]$. In this way, all candidate points of discontinuity in $(\chi_j^0, \chi_j^1]$

are identified and collected in set Ξ . The points of discontinuity that appear in $(\chi_j^0, \chi_j^1]$ also repeat to the right of χ_j^1 with a unit period. It then suffices to sort the potential points of discontinuity identified over $(\chi_j^0, \chi_j^1]$ to obtain the length ϵ_j of the smallest interval along each axis j over which $\Psi^s(\chi_j)$ is guaranteed to be constant for all s . The finally chosen value of ϵ is strictly smaller than each ϵ_j .

We next show that (LB) is a valid lower bounding problem. Note that the feasible region of (LB) is closed, so that a minimizer exists.

Proposition 5.1. *For any partition $\mathcal{P}^k = (l^k, u^k]$,*

$$\beta^k := f_L(\mathcal{P}^k) \leq \inf\{f(\chi) \mid \chi \in \mathcal{P}^k \cap \mathcal{X}\}.$$

Proof: The claim obviously holds if $\mathcal{P}^k \cap \mathcal{X} = \emptyset$. Now consider some $\bar{\chi} \in \mathcal{P}^k \cap \mathcal{X}$. Let $\bar{x} \in \operatorname{argmin}\{cx \mid Tx = \bar{\chi}, x \in X\}$ and $\bar{\theta} = \sum_{s=1}^S p^s \Psi^s(\bar{\chi})$ for all s . Thus, $f(\bar{\chi}) = \Phi(\bar{\chi}) + \sum_{s=1}^S p^s \Psi^s(\bar{\chi}) = c\bar{x} + \bar{\theta}$. We shall now show that $(\bar{x}, \bar{\chi}, \bar{\theta})$ is feasible to (LB). \bar{x} and $\bar{\chi}$ are obviously feasible. From the construction of ϵ and definition of l^k , we know that for each s , $\Psi^s(\chi)$ is constant over $(l^k, l^k + \epsilon]$. Then, owing to the monotonicity property of Ψ^s (Lemma 4.1), $\Psi^s(\bar{\chi}) \geq \Psi^s(l^k + \epsilon)$ since $\bar{\chi} > l^k$. Thus, $\bar{\theta} = \sum_{s=1}^S p^s \Psi^s(\bar{\chi}) \geq \sum_{s=1}^S p^s \Psi^s(l^k + \epsilon)$ and the constraint (6) in (LB) is satisfied. Since the solution is feasible, $f_L(\mathcal{P}^k) \leq c\bar{x} + \bar{\theta} = f(\bar{\chi})$. The claim follows from the fact that the above holds for any $\chi \in \mathcal{P}^k \cap \mathcal{X}$. \square

To solve (LB), we first need to solve S second stage subproblems (7) to construct the cut (6). The master problem (5) can then be solved with respect to the variables (x, χ, θ) . Note that X is typically polyhedral, so that (5) is a linear program. If the first-stage variables have integrality requirements, then (5) is a mixed-integer linear program. Each scenario subproblem and the master problem can be solved completely independently, so complete stage and scenario decomposition is achieved. Problem (5) is similar to the master problem of the L-shaped decomposition method for stochastic linear programs [54]. The variable θ approximates the expected second stage value function in the first stage variable space through constraint (6). In Section 7, we shall discuss how tighter approximations to the value function may be accommodated along with the “lower corner cut” (6).

Proposition 5.2. *Let \mathcal{P}^k be a partition over which the second stage expected value function $\bar{\Psi}(\cdot)$ is constant and there exists $\chi^* \in \operatorname{argmin}\{f(\chi) \mid \chi \in \mathcal{X} \cap \mathcal{P}^k\}$, i.e., the infimum is achieved. Let χ^k be an optimal solution to the lower bounding problem (LB) over this partition. Then,*

$$f(\chi^k) \leq f(\chi^*).$$

Proof: Let (x^k, χ^k, θ^k) be an optimal solution of the lower bounding problem (LB) for the partition $\mathcal{P}^k = (l^k, u^k]$. Note that $\chi^k \in \mathcal{X} \cap \text{cl}(\mathcal{P}^k)$. Then, $f_L(\mathcal{P}^k) = cx^k + \overline{\Psi}(l^k + \epsilon)$ and $f(\chi^k) = cx^k + \overline{\Psi}(\chi^k)$. If $\chi^k > l^k$, then $\overline{\Psi}(\chi^k) = \overline{\Psi}(l^k + \epsilon)$ since $\overline{\Psi}(\cdot)$ is constant over \mathcal{P}^k . Thus, $f(\chi^k) = f_L(\mathcal{P}^k)$. On the other hand, if $\chi_j^k = l_j^k$ for some $j = 1, \dots, m_2$, then $\overline{\Psi}(\chi^k) \leq \overline{\Psi}(l^k + \epsilon)$, owing to the monotonicity property. Thus $f(\chi^k) \leq f_L(\mathcal{P}^k)$. Since $f_L(\mathcal{P}^k) \leq f(\chi^*)$ by Proposition 5.1, the claim follows. \square

5.4 Upper Bounding

For a given partition \mathcal{P}^k such that $\mathcal{P}^k \cap \mathcal{X} \neq \emptyset$, let χ^k be an optimal solution of problem (LB). Note that $\chi^k \in \mathcal{X}$, and is therefore a feasible solution. We can then compute an upper bound

$$\alpha^k := f(\chi^k) \geq \min\{f(\chi) | \chi \in \mathcal{X}\}.$$

Proposition 5.3. *If, for a partition \mathcal{P}^k , the second stage expected value function $\overline{\Psi}(\cdot)$ is constant, then the partition \mathcal{P}^k will be fathomed in the course of the algorithm.*

Proof: From the proof of Proposition 5.2, $\alpha^k = f(\chi^k) \leq f_L(\mathcal{P}^k) = \beta^k$. In the bounding Step k.2.a of the algorithm, we set $U = \min\{U, \alpha^k\}$. Thus, in Step k.2.c, the current partition \mathcal{P}^k satisfies $\beta^k \geq U$ and will be fathomed. \square

5.5 Branching

A typical scheme for partitioning \mathcal{P}^k would consist of selecting and bisecting the variable j' corresponding to the longest edge of the hyper-rectangle \mathcal{P}^k . Although such a scheme is *exhaustive* [52], it might not be possible to isolate partitions without discontinuities, and take advantage of Proposition 5.3.

To isolate the discontinuous pieces of the second stage value function, we are required to partition an axis j' at a point $\chi_{j'}$ such that $\Psi^s(\cdot)$ is possibly discontinuous at $\chi_{j'}$ for some s . While we can do this by selecting $\chi_{j'}$ such that $h_{j'}^s + \chi_{j'}$ is integral for some s , we can do better by determining the value of $\chi_{j'}$ where the current second stage solution becomes infeasible. Such a point is more likely to be one at which $\Psi^s(\cdot)$ is discontinuous. This scheme is formally stated next. We let y^s be the solution of the second stage IP subproblems in the solution of the lower bounding problem (LB).

The branching scheme

- For each $j = 1, \dots, m_2$, compute $p_j := \min_{s=1, \dots, S} \{(D^s y^s)_j - h_j^s\}$.
- Let $j' \in \text{argmax}_j \{p_j - l_j^k\}$.

- Split $\mathcal{P}^k = \prod_{j=1}^{m_2} (l_j^k, u_j^k]$ into two partitions $\mathcal{P}^{k_1} = (l_{j'}^k, p_{j'}] \prod_{j \neq j'} (l_j^k, u_j^k]$, and $\mathcal{P}^{k_2} = (p_{j'}, u_{j'}^k] \prod_{j \neq j'} (l_j^k, u_j^k]$.

6 Proof of Finiteness

Consider a nested sequence of successively refined partitions $\{\mathcal{P}^{k_q}\}$ such that $\mathcal{P}^{k_{q+1}} \subset \mathcal{P}^{k_q}$.

Definition 6.1. [22] *A bounding operation is called finitely consistent if, at every step any unfathomed partition element can be further refined, and if any nested sequence of $\{\mathcal{P}^{k_q}\}$ of successively refined partition elements is finite.*

Lemma 6.2. *In a branch and bound procedure, suppose that the bounding operation is finitely consistent. Then, the procedure terminates after finitely many steps.*

Proof: See Theorem IV.1. in [22]. □

Lemma 6.3. *The bounding operation of the proposed branch and bound algorithm is finitely consistent.*

Proof: Consider a partition \mathcal{P}^k that is unfathomed. By Proposition 5.3, the second stage value function is discontinuous over this partition. Thus, the branching step can further refine it, thereby satisfying the first condition for finite consistency. Branching along the discontinuity on this partition will result in two strictly smaller partitions. By Theorem 4.5, the number of discontinuities in \mathcal{P}^k is finite. Therefore, any nested sequence $\{\mathcal{P}^{k_q}\}$ generated by branching along the discontinuities of \mathcal{P}^k will be finite. □

Theorem 6.4. *The proposed algorithm terminates with a global minimum after finitely many steps.*

Proof: As a consequence of Lemmas 6.2 and 6.3, it follows that the algorithm terminates after finitely many steps. The globality of the solution follows from the validity of the lower and upper bounding procedures used. In particular, let $\chi^* \in \mathcal{P}^0$ be a global minimizer. Then, there exists a finite nested sequence $\{\mathcal{P}^{k_q}\}_{q=1}^Q$ of length Q such that $\chi^* \in \mathcal{P}^{k_q}$ for all $q = 1, 2, \dots, Q$. Clearly, \mathcal{P}^{k_Q} does not contain a discontinuity, otherwise it would be further refined. Furthermore, $\chi^* \in \operatorname{argmin}\{f(\chi) | \chi \in \mathcal{X} \cap \mathcal{P}^{k_Q}\}$. Let χ^k be the solution to the lower bounding problem over \mathcal{P}^{k_Q} . Then, by Proposition 5.2, $f(\chi^k) \leq f(\chi^*)$. Since $\chi^k \in \mathcal{X}$, χ^k must also be a global minimizer. □

7 Enhancements and Extensions

The proposed branch and bound algorithm is valid for any lower bounding scheme that dominates the lower bound obtained by solving problem (LB). In this section, we suggest how such tighter bounds may be obtained. We also discuss the applicability of the proposed algorithm in case of mixed-integer second stage variables.

Benders cuts

Consider the LP relaxation of the second stage problem for a given scenario s and a value of the tender variable $\bar{\chi}$:

$$\begin{aligned} \Psi_{LP}^s(\bar{\chi}) = \min \quad & f^s y \\ \text{s.t.} \quad & D^s y \geq h^s + \bar{\chi} \quad (\bar{u}^s) \\ & y \geq 0 \end{aligned}$$

where the \bar{u}^s are the optimal dual solutions. We assume that the constraint $y \in Y$ is included in the constraint $D^s y \geq h^s + \bar{\chi}$. The classical Benders cut [2] is then given by:

$$(h^s + \chi)\bar{u}^s \leq \Psi_{LP}^s(\chi),$$

and is valid for any χ (not just $\bar{\chi}$). Since $\Psi_{LP}^s(\chi) \leq \Psi^s(\chi)$, we also have

$$\sum_{s=1}^S p^s [(h^s + \chi)\bar{u}^s] \leq \sum_{s=1}^S p^s \Psi^s(\chi).$$

Thus, if we have dual solutions u^s for the LP relaxations of the second stage problem corresponding to any χ , we can add the valid cut

$$\theta \geq \sum_{s=1}^S p^s [(h^s + \chi)\bar{u}^s]$$

to our lower bounding problem (LB). These, along with the “lower corner cuts” (6), may provide a better approximation to the second stage value function.

Bounds from the Lagrangian Dual

Caroe [9, 11] used the scenario decomposition approach of Rockafellar and Wets [39] to obtain bounds for (2SSIP). The idea here is introduce copies x^1, \dots, x^S and y^1, \dots, y^S of the first stage and second stage variables, corresponding to each scenario, and then rewrite (2SSIP) in the form

$$\begin{aligned} \min \quad & \sum_{s=1}^S p^s c x^s + p^s f^s y^s \\ \text{s.t.} \quad & x^s \in X \quad s = 1, \dots, S \\ & D^s y^s \geq h^s + T x^s \quad s = 1, \dots, S \\ & y^s \in Y \cap \mathbb{Z}^{n_2} \quad s = 1, \dots, S \\ & x^1 = \dots = x^S \end{aligned} \tag{8}$$

Above, the *non-anticipativity* constraint (8) states that the first stage decision should not depend on the scenario which will prevail in the second stage. This constraint can also be represented as $\sum_{s=1}^S H^s x^s = 0$, where H^s are matrices of conformable dimensions (see [9] for details). The Lagrangian relaxation with respect to the non-anticipativity constraints is then,

$$\begin{aligned} L(\lambda) = \min & \sum_{s=1}^S (p^s c + \lambda H^s) x^s + p^s f^s y^s \\ \text{s.t.} & x^s \in X \quad s = 1, \dots, S \\ & D^s y^s \geq h^s + T x^s \quad s = 1, \dots, S \\ & y^s \in Y \cap \mathbb{Z}^{n_2} \quad s = 1, \dots, S. \end{aligned}$$

Since the above problem is completely decomposable by scenarios, we can equivalently write it as:

$$L(\lambda) = \sum_{s=1}^S \min \{ (p^s c + \lambda H^s) x^s + p^s f^s y^s \mid x^s \in X, D^s y^s \geq h^s + T x^s, y^s \in Y \cap \mathbb{Z}^{n_2} \}.$$

It is well known that the Lagrangian dual $z_{LD} = \max_{\lambda} L(\lambda)$ provides a lower bound to (2SSIP). Caroe used this lower bounding scheme within a branch and bound framework for solving (2SSIP).

Since we partition the space of tender variables, consider the Lagrangian relaxation of the problem when the tender variables are restricted to be $\chi \in \mathcal{P} := (l, u]$:

$$\begin{aligned} L(\lambda, \mathcal{P}) = \sum_{s=1}^S \min & \{ (p^s c + \lambda H^s) x^s + p^s f^s y^s \mid x^s \in X, l \leq T x^s \leq u, \\ & D^s y^s \geq h^s + T x^s, D^s y^s \geq h^s + l + \epsilon, y^s \in Y \cap \mathbb{Z}^{n_2} \}, \end{aligned}$$

where ϵ is the same as that considered in problem (LB) in Section 5.3. Note that the above Lagrangian relaxation has additional constraints: $D^s y^s \geq h^s + l + \epsilon$, to deal with the neither open nor closed nature of \mathcal{P} . We shall denote the corresponding Lagrangian dual by

$$z_{LD}(\mathcal{P}) := \max_{\lambda} L(\lambda, \mathcal{P}).$$

Proposition 7.1. *Given a partition $\mathcal{P} := (l, u]$,*

$$f_L(\mathcal{P}) \leq z_{LD}(\mathcal{P}) \leq \inf \{ f(\chi) \mid \chi \in \mathcal{X} \cap \mathcal{P} \}.$$

Proof: Let $(\bar{x}^1, \dots, \bar{x}^S, \bar{y}^1, \dots, \bar{y}^S)$ be the solutions obtained while computing $L(0, \mathcal{P})$. Thus

$$L(0, \mathcal{P}) = \sum_{s=1}^S p^s c\bar{x}^s + p^s f^s \bar{y}^s.$$

Let \tilde{x} be the solution of the master problem (5), and \tilde{y}^s be the solution of the scenario s subproblem (7), while computing $f_L(\mathcal{P})$. Since each \bar{x}^s is feasible to the master problem (5), we have $c\tilde{x} \leq c\bar{x}^s$ for all s . Thus, $c\tilde{x} \leq \sum_{s=1}^S p^s c\bar{x}^s$. Recall that the subproblems (7) are solved with $\chi = l + \epsilon$, *i.e.*, with the constraint $D^s y \geq h^s + l + \epsilon$. Since \bar{y}^s also satisfies $D^s \bar{y}^s \geq h^s + l + \epsilon$, \bar{y}^s is feasible to the scenario s subproblems (7), and so $f^s \tilde{y}^s \leq f^s \bar{y}^s$ for each s . Clearly,

$$\begin{aligned} f_L(\mathcal{P}) &= \sum_{s=1}^S p^s c\tilde{x} + p^s f^s \tilde{y}^s \\ &\leq \sum_{s=1}^S p^s c\bar{x}^s + p^s f^s \bar{y}^s \\ &= L(0, \mathcal{P}) \\ &\leq z_{LD}(\mathcal{P}). \end{aligned}$$

To see that $z_{LD}(\mathcal{P}) \leq \inf\{f(\chi) | \chi \in \mathcal{X} \cap \mathcal{P}\}$, consider a feasible solution $(\chi, x, y^1, \dots, y^S)$ such that $\chi = Tx$, $x \in X$, $\chi \in \mathcal{X} \cap \mathcal{P}$, and $D^s y^s \geq h^s + \chi$ for all s . Construct a solution $(\bar{x}^1, \dots, \bar{x}^S, \bar{y}^1, \dots, \bar{y}^S)$ to the Lagrangian relaxation $L(\lambda, \mathcal{P})$, by setting $\bar{x}^s = x$, and $\bar{y}^s = y^s$ for all s . To see that such a solution is feasible to $L(\lambda, \mathcal{P})$, we only need to verify that $D^s \bar{y}^s \geq h^s + l + \epsilon$. Since $T\bar{x}^s = \chi > l$, and from the definition of ϵ , $\lceil h^s + T\bar{x}^s \rceil$ is constant whenever $T\bar{x}^s \in (l, l + \epsilon]$, we have that $D^s \bar{y}^s \geq h^s + T\bar{x}^s$ implies $D^s \bar{y}^s \geq h^s + l + \epsilon$. Thus the solution $(\bar{x}^1, \dots, \bar{x}^S, \bar{y}^1, \dots, \bar{y}^S)$ is feasible to $L(\lambda, \mathcal{P})$. Since $\bar{x}^1 = \dots = \bar{x}^S$, we have $\sum_{s=1}^S H^s \bar{x}^s = 0$, and $\sum_{s=1}^S \{(p^s c + \lambda H^s) \bar{x}^s + p^s f^s \bar{y}^s\} = c(\sum_{s=1}^S p^s \bar{x}^s) + \sum_{s=1}^S p^s f^s \bar{y}^s = cx + \sum_{s=1}^S p^s f^s y^s$. Thus $L(\lambda, \mathcal{P}) \leq \inf\{f(\chi) | \chi \in \mathcal{X} \cap \mathcal{P}\}$. Since the λ was arbitrary, the inequality is true for $z_{LD}(\mathcal{P})$. \square

Thus, we can use the Lagrangian dual to obtain tighter bounds than those obtained by solving (LB).

Mixed-integer Second Stage

In the presence of continuous variables in the second stage, the orthogonality of the discontinuities in the space of the tender variables may be lost. Consider, for example, a variant of (EX) where the second stage problem (in the space of the tender variables) is given by:

$$\begin{aligned} Q(\chi_1, \chi_2, \omega_1, \omega_2) = \min \quad & -16y_1 - 19y_2 - 23y_3 - 28y_4 \\ \text{s.t.} \quad & 2y_1 + 3y_2 + 4y_3 + 5y_4 \leq \omega_1 - y_5 \\ & 6y_1 + y_2 + 3y_3 + 2y_4 \leq \omega_2 - y_6 \end{aligned}$$

$$\begin{aligned}
-1.9706y_5 + 0.9706y_6 &\leq -\chi_1 \\
0.9706y_5 - 1.9706y_6 &\leq -\chi_2 \\
y_1, y_2, y_3, y_4 &\in \{0, 1\} \\
y_5, y_6 &\in [0, 5].
\end{aligned}$$

The expected second stage value function (with $\Omega = \{0, 5\} \times \{0, 5\}$ with uniform probability) in the space of the χ variables is shown in Figure 4.

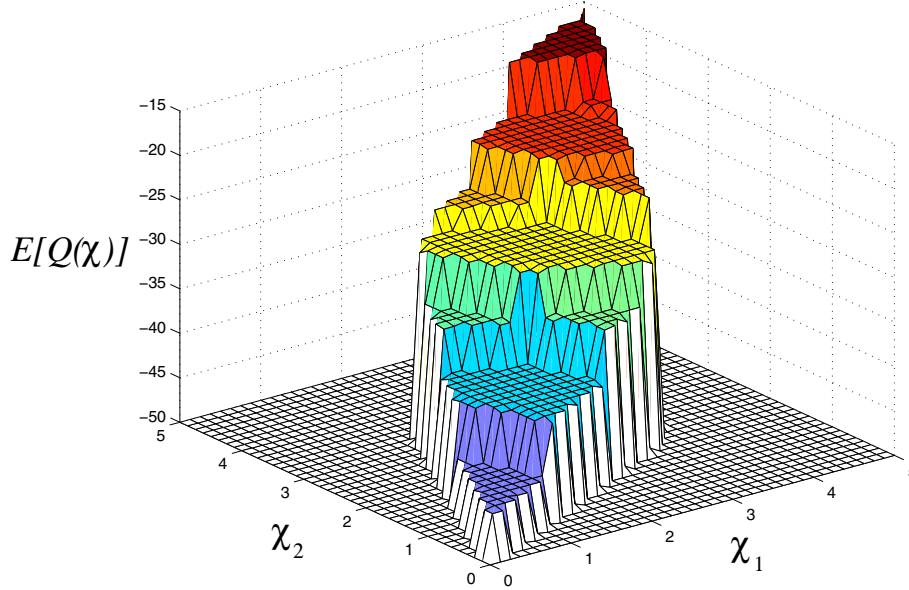

Figure 4: Mixed integer second stage

Since the discontinuities of the second stage mixed-integer value function are no longer orthogonal, finiteness of the algorithm cannot be achieved with a rectangular partitioning scheme. In principle, one could reformulate the problem by including all the continuous variables from the second stage subproblems in the first stage, thereby ending up with a pure integer second stage. The finiteness of the proposed algorithm would be retained when applied to this reformulation. Since such a scheme would involve branching on continuous variables from the first stage problem as well as those from the scenario subproblems, the method would only be viable when there are only a few continuous variables per second stage subproblem. Another straight forward way of ensuring finiteness is to consider explicitly branching on the integer variables of the second stage. Even though this will be computationally intensive, it will also guarantee finite termination.

Blair and Jeroslow [8] proved that the value function of a mixed-integer program is piece-wise polyhedral over certain cones in the space of the right-

hand side vectors. At this point, it is not obvious how one can use these results to design a partitioning scheme that guarantees finiteness of the branch and bound algorithm.

Random Technology Matrix

The proposed algorithm can be extended to problems where the technology matrix T is scenario-dependent by introducing tender variables corresponding to each scenario, *i.e.*, $\chi^s = T^s x$. However, in this case, the algorithm would require branching on $S \times m_2$ variables as opposed to m_2 variables when T is deterministic.

8 Computational Results

In this section, we report our computational experience in using the proposed branch and bound algorithm to solve instances of two-stage stochastic integer programs from the literature.

Test Set 1

The first set of test problems involves two-stage stochastic integer programs with pure integer first stage variables taken from Caroe [9]. Since the first stage variables are pure integer, Caroe’s method terminates finitely. However, our computational results indicate that the proposed method is much faster than Caroe’s algorithm even for this problem class. The test problems are generated from the following basic model:

$$\begin{aligned} \text{(EX1)} : \quad & \min \quad -1.5x_1 - 4x_2 + E[Q(x_1, x_2, \omega_1, \omega_2)] \\ & \text{s.t.} \quad x_1, x_2 \in [0, 5] \cap \mathbb{Z}, \end{aligned}$$

where

$$\begin{aligned} Q(x_1, x_2, \omega_1, \omega_2) = \quad & \min \quad -16y_1 - 19y_2 - 23y_3 - 28y_4 \\ & \text{s.t.} \quad 2y_1 + 3y_2 + 4y_3 + 5y_4 \leq \omega_1 - x_1 \\ & \quad \quad 6y_1 + y_2 + 3y_3 + 2y_4 \leq \omega_2 - x_2 \\ & \quad \quad y_1, y_2, y_3, y_4 \in \{0, 1\}, \end{aligned}$$

where (ω_1, ω_2) is uniformly distributed on $\Omega \subseteq [5, 15] \times [5, 15]$. Five test problems are generated from the above instance by varying the number of scenarios by taking Ω as equidistant lattice points in $[5, 15] \times [5, 15]$ with equal probability assigned to each point. The resulting instances have 4, 9, 36, 121, and 441 scenarios. The size of the deterministic equivalent for each of these instances is shown in Table 1.

Caroe [9] reports attempts to directly solve the deterministic equivalent of the above instances using the MIP solver of CPLEX 5.0. With 36 or more

Scenarios	Integer Variables	Binary Variables	Constraints
4	2	16	8
9	2	36	18
36	2	144	72
121	2	484	242
441	2	1764	882

Table 1: Sizes of instances in Test Set 1

scenarios, CPLEX 5.0 MIP could not solve the problem instances within resource usage limits. For example, the instance with 121 scenarios could not be solved within 300,000 nodes, yielding an optimality gap of more than 10%. These results clearly motivate the need for decomposition-based approaches.

The proposed algorithm was applied to solve this small example. Since the second stage integer subproblems involved only 4 binary variables, they were solved by complete enumeration. The computations were carried out on a 332 MHz IBM RS/6000 PowerPC. Table 2 compares the performance of the proposed algorithm to that of the Lagrangian decomposition approach of Caroe [9]. A major part of the computational effort in solving stochastic integer programs is spent on solving IP subproblems. From Table 2, it is clear that the number of IPs solved is fewer for the proposed method. Furthermore, the IP subproblems only correspond to second stage problem, whereas for Caroe’s method, these involve first stage variables as well. Consequently, the CPU requirements of the proposed method are much lesser. Note that the platforms used in the two computations are different. To keep the CPU times in perspective, Table 3 compares the relative performance of the two machines on standard benchmarks as listed on [24] and [16]. The benchmarks reflect the performance of the microprocessor, memory architecture, and the compiler. SPECint95 is a component level benchmark established by the Standard Performance Evaluation Corporation [48], that measures integer performance. SPECfp95 is a similar benchmark measuring floating-point performance. These benchmarks reflect the ratio of a base CPU requirement to the CPU requirement of the hardware to perform some standard computations. Thus, a higher benchmark value indicates superior performance. The LINPACK benchmark provides the speed with which a dense system of 100 linear equations is solved using the LINPACK [15] libraries in a FORTRAN environment. From the benchmark values in Table 3, it is clear that the platform used by Caroe [9] is faster. Therefore, the computational results in Table 2 indicate that the proposed algorithm is much faster than that of [9].

Test Set 2

Our second test set is taken from Schultz *et al.* [45]. It consists of two variants of (EX1) (described in Test Set 1) with continuous first stage variables. The first of these problems (Example 7.1 in [45]) is the 441 scenario version of (EX1)

Scenarios	Caroe [9]			Proposed		
	CPU* s.	IPs solved	Obj.	CPU† s.	IPs solved	Obj.
4	0.2	52	57.00	0.01	52	57.00
9	0.4	189	59.33	0.01	135	59.33
36	1.4	720	61.22	0.01	540	61.22
121	4.8	2783	62.29	0.02	1936	62.29
441	25.1	9702	61.32	0.06	7056	61.32

* Digital Alpha 500 MHz
† IBM RS/6000 43P 332 MHz

Table 2: Computational results for Test Set 1

Benchmark	Digital Alpha 500 [16]	IBM RS/6000 Model 43P [24]
SPEC int95	15.0	12.9
SPEC fp95	20.4	6.21
LINPACK DP ($n = 100$)	235.3 Mflop/s	59.9 Mflop/s
Clock speed	500 MHz	332 MHz

Table 3: Comparative performance of hardware

	CPLEX 5.0 [45]		Schultz <i>et al.</i> [45]		Proposed	
	Nodes	Gap	IPs solved	Obj.	IPs solved	Obj.
Problem 1 ($T = I$)	50000	24%	53361	61.32	12248	61.32
Problem 2 ($T \neq I$)	50000	27%	8379	61.44	4410	61.44

Table 4: Comparative performance for Test Set 2

with the integrality restrictions removed from the first stage variables. Schultz *et al.* [45] identified the set of candidate solutions to be the finite set $\{(k_1/2, k_2/2) : k_1, k_2 \in \mathbb{Z}\} \cap [0, 5] \times [0, 5]$. This set has a cardinality of 121, and the authors evaluated each of these points to determine the optimal solution $x_1 = 0, x_2 = 4$ with value 61.32. Note that evaluating a single point amounts to solving 441 second stage integer programs. Therefore, a total of 53,361 small integer programs were solved in [45]. These problems were solved using Gröbner basis methods. [45] also reports their attempt to solve this problem by CPLEX 5.0 with a node limit of 50,000. After exploring all 50,000 nodes, CPLEX ended up with an optimality gap of 24%. No CPU times were reported in Schultz *et al.* [45].

We solved the problem to global optimality using the proposed branch and bound algorithm. The algorithm required the solution of only 12,348 second stage integer programs – a reduction of 76% in the number of IPs solved than that required by [45].

Note that, in (EX1), the technology matrix T is the identity. To illustrate the effect of the variable transformation, we next solve another variant of (EX1) with a more interesting T matrix, namely problem (EX) (described in Section 1) with 441 scenarios. Schultz *et al.* [45] solved this problem (Example 7.3 in [45]) by characterizing the solution set and identifying 53 candidate points. Using

Scenarios	Problem 1 ($T = I$)			Problem 2 ($T \neq I$)		
	CPU [†] s.	IPs solved	Obj.	CPU [†] s.	IPs solved	Obj.
4	0.01	60	57.00	0.00	24	57.75
9	0.01	171	59.33	0.00	63	59.56
36	0.02	684	61.22	0.01	396	60.28
121	0.03	2299	62.29	0.02	1331	61.01
441	0.15	12348	61.32	0.05	4410	61.44

Table 5: Computational results for Test Set 2

some problem specific results, they were able to reduce the number of candidate points to 19. Complete enumeration of these points required the solution of 8379 integer subproblems, and yielded the optimal solution of $x_1 = 0, x_2 = 4.5$ with objective value 61.44. On the other hand, the proposed branch and bound algorithm required the solution of only 4410 integer programming subproblems – a 47% reduction in the number of IPs solved. For this problem, Schultz *et al.* [45] reports that CPLEX with a node limit of 50,000 ended up with an optimality gap of 27%.

The comparative performances discussed above are summarized in Table 4. Both of these problems include 441 scenarios. Table 5 presents the CPU times and the number of IP subproblems required by the proposed algorithm for solving various scenario instances of the two problems in Test set 2.

Test Set 3

Our final test set is a collection of two-stage stochastic product substitution problems described in Woodruff *et al.* [27, 35]. The problem involves mixed-integer variables in both first and second stage. The set includes three problems, SIZES3, SIZES5, and SIZES10, having 3, 5, and 10 scenarios. The size of the deterministic equivalent integer program for each of these test problems are presented in Table 6.

A direct attempt to solve the deterministic mixed-integer program using the CPLEX 5.0 MIP solver was reported in Jorjani *et al.* [27]. These results are summarized in Table 7. The authors put a node limit of 20,000 for the two smaller problems, and 250,000 for the larger problem. Even after exploring such large number of nodes, CPLEX could not solve these problems and yielded optimality gaps in the range of 2-4%. From this table, it is clear that, although the problems are of modest size (no more than 110 binary variables), they are not amenable to state-of-the-art integer programming techniques, and one must rely on decomposition methods.

Caroe [9] attempted to solve these problems using Lagrangian decomposition based branch and bound algorithm. A CPU limit of 1000 seconds was imposed. Until now, Caroe’s results were the best available for these problems.

Having gained some insight regarding the applicability of the proposed method on problems with mixed-integer second stage (Section 7), we attempted to solve

Problem	Binary Variables	Continuous Variables	Constraints
SIZES3	40	260	142
SIZES5	60	390	186
SIZES10	110	715	341

Table 6: Sizes of Test Set 3

these problems by explicitly branching on the second stage integer variables. The implementation was carried out using BARON [42, 51] to maintain the branch and bound tree. OSL [23] was used as the IP solver and CPLEX [13] was used as the LP solver. The computations were carried out on a 332MHz IBM Rs/6000 PowerPC. A CPU limit of 100,000 seconds was imposed.

Problem	LB	UB	Nodes	CPU [†] s
SIZES3	218.2	224.7	20000	1859.8

Problem	Total Nodes	Max. Nodes in memory	Nodes until best UB
SIZES3	1885	260	906
SIZES5	108,782	13,562	41,642
SIZES10	36,700	23,750	20,458

Table 9: Nodes in branch and bound tree

Table 8 compares the performance of the proposed method with that of [9]. As a reference, the node information required by our branch and bound algorithm is presented in Table 9. From Table 8, we observe that Caroe’s method was not able to close the gap for these problems on a computer much faster than ours. The proposed approach successfully closed the gap for two of these three very difficult problems. For all three test problems, we were able to identify better upper bounds (feasible solutions) than those known earlier.
